(57) Current portable radiotelephones generally comprise at least a numeric keypad, for composing telephone numbers, and a number of additional function keys, for initiating communications to a desired telephone number, turning the radiotelephone on and off etc. It is also common for the numeric keypad to also contain alphabetic representations, for allowing the construction of textual messages. Typically, each numeric key represents three alphabetic characters, for example, the numeric key '2' often also represents characters 'A', 'B' and 'C'. During the construction of a textual message, each press of a numeric key causes a display to cycle through each character represented by that key. For example, a first press of numeric key '2' would cause the character 'A' to be displayed, a second press would cause the character 'B' to be displayed and so on. When the desired character is displayed, a further character may be entered either after a short delay, or by pressing another key. In this way textual messages may be constructed. A textual message may then be transmitted to another user in a variety of ways which will be apparent to those skilled in the art.

One problem with the above method is that the construction of textual messages is somewhat arduous since each key may require multiple presses in order to select the required character.

The present invention aims to provide improved data input.

**FIG.7**

## Description

[0001] The present invention relates to the field of portable radiotelephones, and more particularly, for inputting data into such devices.

[0002] Current portable radiotelephones provide a host of features in addition to that of making and receiving telephone calls. Such additional features include the storing and retrieving of telephone numbers and names from an internal phone book, to the sending of textual messages to other users.

[0003] Current portable radiotelephones generally comprise at least a numeric keypad, for composing telephone numbers, and a number of additional function keys, for initiating communications to a desired telephone number, turning the radiotelephone on and off etc. It is also common for the numeric keypad to also contain alphabetic representations, for allowing the construction of textual messages. Typically, each numeric key represents three alphabetic characters, for example, the numeric key '2' often also represents characters 'A', 'B' and 'C'. During the construction of a textual message, each press of a numeric key causes a display to cycle through each character represented by that key. For example, a first press of numeric key '2' would cause the character 'A' to be displayed, a second press would cause the character 'B' to be displayed and so on. When the desired character is displayed, a further character may be entered either after a short delay, or by pressing another key. In this way textual messages may be constructed. A textual message may then be transmitted to another user in a variety of ways which will be apparent to those skilled in the art.

[0004] One problem with the above method is that the construction of textual messages is somewhat arduous since each key may require multiple presses in order to select the required character.

[0005] In order to overcome this problem, some radiotelephones now comprise typewriter style keyboards. Whilst allowing the easier entry of text, such keyboards are large and cumbersome. Radiotelephones incorporating such keyboards are thus also large. Reducing the size of such a keyboard, however, makes it increasingly difficult to select the required key, since the keys of the keyboard become smaller than the size of a finger tip, and results in an increased chance of the wrong key being pressed.

[0006] Accordingly, one aim of the present invention is to provide improved data input means for use with a portable radiotelephone.

[0007] According to a first aspect of the present invention, there is provided apparatus for selecting a character from a predetermined set of characters comprising: means for presenting to a user a first plurality of selectable choices, at least one of which represents a sub-set of said set of characters; input means for selecting one of said first plurality of selectable choices; means for presenting to a user a second plurality of selectable

choices, at least one of which represents a character of said selected sub-set; and means for selecting a character.

[0008] According to a second aspect of the present invention, there is provided a method of selecting a character from a predetermined set of characters comprising: presenting to a user a first plurality of selectable choices, at least one of which represents a sub-set of said set of characters; selecting one of said first plurality of selectable choices; presenting to a user a second plurality of selectable choices, at least one of which represents a character of said selected choice; and selecting a character from said second plurality of selectable choices.

[0009] This has the advantage of allowing easy entry of alphanumeric data into a portable radiotelephone without requiring a large keyboard. Additionally, the requirement for multiple presses of numeric keys associated with alphabetic characters is also removed. The present invention is particularly advantageous for portable radiotelephones or similar devices which do not have a keyboard due to their small size. In addition, the present invention provides a quick, accurate and efficient way of entering data in a single-handed operation.

[0010] The present invention also has advantages over pen-entry systems, such as character recognition systems, wherein a pen-like element is wiped over a touch sensitive pad and a controller attempts to interpret the movements made in order to recognise the character being written. These systems are inherently slow and difficult to use and require the user to make precise movements to ensure the correct character is recognised. Failure to make precise movements often leads to the recognition of an erroneous character. In such systems, the pen-like element is easily lost, rendering data input extremely difficult.

[0011] Advantageously, the number of selectable choices presented to the user is limited to the number of defined positions of the input device. By the limiting the number of selectable choices in this way, and by arranging the presentation of the selectable choices according to the positions of the input device allows any selectable choice to be made with only one user input.

[0012] The present invention may also be implemented to allow full or partial control of a portable radiotelephone, thereby eliminating the need for a data input keypad.

[0013] The present invention will now be described, by way of example only, with reference to the accompanying drawings, in which:

Figure 1 is a diagram showing a representation of the directional input controls of a joystick input device;

Figure 2 is a diagram showing a typical character set for use with a portable radiotelephone;

Figure 3 is a diagram showing an arrangement of menu items and submenus according to one em-

bodiment of the present invention.

Figure 4 is a diagram showing a further arrangement of menu items and submenus according to a further embodiment of the present invention;

Figure 5 is a block diagram showing a portable radiotelephone according to the present invention;

Figure 6 is a flow diagram showing an example of how the controller of Figure 5 operates according to one embodiment of the present invention; and

Figure 7 shows a number of portable radiotelephones incorporating the present invention.

**[0014]** Figure 1 is a diagram showing a representation of the directional input controls of a joystick device having nine defined positions 100 to 108. The joystick device shown allows 8 directional control signals to be generated, depending on the position of the joystick device. Additionally, the joystick device acquires a neutral position 108, when no force is applied thereto. The joystick device as shown may be implemented using a switch array, which allows directional control signals to be generated dependent on the direction in which the joystick device is moved. Those skilled in the art will appreciate that many configurations of joystick device may be used in lieu of that described above. For instance, an analogue joystick device which uses one or more potentiometers to derive a x and y-axis displacement may also be used, with suitable control circuitry. It will also be apparent that a joystick device having more or less defined positions, including a mouse or track-wheel, will also be suitable without detracting from the inventive concepts of the present invention. Further, an arrangement of cursor keys capable of generating suitable directional control signals will also be suitable.

**[0015]** Figure 2 is a diagram showing a typical character set for use with a portable radiotelephone using the English language. Characters  $X_1$  to  $X_{11}$  represent special characters which can be used, for example, for foreign or accented characters, mathematical symbols, etc.

**[0016]** Figure 3 is a diagram showing an arrangement of menu items and submenus according to one embodiment of the present invention. Figure 3a shows a first menu screen which is presented to a user when alphanumeric entry is required by a portable radiotelephone, such as when composing a textual message to be sent to another user. The menu screen is presented, on a display device such as an LCD screen, as a matrix of blocks 301 to 309, the arrangement of which matches the defined positions of the joystick device of Figure 1. In an alternative embodiment, the matrix is replaced by a series of segments arranged to coincide with positions of the input device. It will be appreciated that the block or segment positions do not have to match the defined positions of the joystick device.

**[0017]** Each of the blocks 301 to 308 represents a sub-set of the character set shown in Figure 2. For example, block 308 represents the characters A to G,

block 306 represents the characters H to N etc. A user may select any one of the blocks 301 to 308 using the joystick device. As the joystick device is pushed, the block which corresponds to the direction in which the joystick device was pushed is highlighted. For example if the user wants to choose the character 'D' for inclusion in a text message, the joystick device is pushed upwards and block 308 is highlighted. Highlighting may take the form of inverting the pixels representing that block, displaying a border around the block, or such like. As the joystick device is moved around, a block is highlighted according to the position of the joystick device. When the desired block is highlighted, the user can select the highlighted block.

**[0018]** In a preferred embodiment of the present invention, the selection of a desired block is achieved by maintaining the joystick device in the position corresponding to the desired block for a given time period. For example, to select the block 308, the user first of all pushes the joystick device upwards, which highlights the block 308. By maintaining the pressure on the joystick device in the same direction for, for example, 0.5 seconds, the highlighted block is selected. The time period required before selection takes place is dependent on user preferences. For example, an experienced user may wish the time period to be decreased, thereby increasing the speed at which data can be input. Alternatively, a novice user may wish the time period to be increased. Preferably, the time period is user selectable, with a default setting of around 0.5 to 1.5 seconds. In another embodiment of the present invention, the user selects a block, after first highlighting the block, by allowing the joystick device to return to its neutral position 108. If the joystick device is left in the neutral position for a short period of time, the currently highlighted block is selected. Alternatively, the user may press a selection button to select the current highlighted block. The selection button may or may not form part of the joystick device, or may be activated by pushing downwards on the joystick device axis.

**[0019]** Once a block is selected, the first menu screen is replaced by a submenu screen. The contents of the submenu screen are dependent on the previous block selected. If, in the above example, the block 308 was selected, the subscreen 2 as shown in Figure 3c will be presented to the user. Each of the blocks of submenu screen 2 represent individual characters. To select a character, the joystick device is moved in the direction of the required character to highlight the appropriate block. Once the required block is highlighted, it may be selected as described above. Once selected, the chosen character can be added to a text message, to enable a textual message to be constructed. The selection of lower-case characters may be implemented by a separate 'shift' key, or they may be represented as individual characters as described above. In an alternative embodiment, the portable radiotelephone displays the first character selected in upper case, and subsequent char-

acters in lower case until a full stop is selected, in which case the next character selected would be displayed in upper case and so on.

[0020] Figures 3b to 3i show examples of a number of submenu screens which may be used according to the present invention. Using the selection methods outlined above, it is clear how any character from the character set shown in Figure 2 can be selected using only two joystick movements. This provides both a quick and an accurate way of inputting alphanumeric characters to a device such as a portable radiotelephone. Through practice, a user may quickly become adept in selecting the desired characters through appropriate joystick movements, much in the way that writing is learned. In particular, this method of data entry is particularly advantageous in portable radiotelephones which do not have a keypad, for example on very small or wearable devices, where the size of an incorporated keypad would be too small to operate using the fingers.

[0021] Each of submenu screens shown in Figure 3 preferably include at least one blank block. Figure 3b, for example, shows the presence of a blank block in the upper left corner. The position of the blank block corresponds to the position which was required to select that submenu screen in the main menu screen. For example, if block 307 of Figure 3a was selected, the top left block in the associated submenu screen will be blank. Correspondingly, if block 308 of Figure 3a was selected, the corresponding block in the associated submenu screen will be blank. This arrangement helps prevent the accidental selection of characters caused by holding the joystick for too long in a given position.

[0022] It is, however, possible for every block in the matrix to be used. Additionally functionality may also be implemented, for example, the provision of a 'back' block, to allow the parent screen of any submenu screen to be presented to the user. This feature is particularly useful when a submenu screen is erroneously selected.

[0023] Figure 3 shows one possible arrangement of the characters in the submenu screens. In an alternative embodiment, improvements to the user interface may be achieved by specific grouping of the characters. For example, by grouping all vowels together in one submenu screen will allow vowels to be selected quickly. Additionally, characters may be grouped according to their distribution in a particular language. For example, the letters 'e, a, i, t,' etc may be grouped together as they occur frequently in the English language.

[0024] It will be appreciated that the invention can also be implemented to control the entire functionality of a portable radiotelephone. Figure 4a shows an example of a menu screen wherein each block represents a menu item for controlling the functionality of a portable radiotelephone.

[0025] For example, if a user wishes to dial a subscriber number and initiate a call, the user would select the 'dial' menu in the manner described above. Selecting the 'dial' menu would cause the arrangement shown in

Figure 4b to be presented to the user. Using the techniques described above, the user can quickly compose a subscriber number and, using the 'send' option, initiate a telephone call with the chosen subscriber.

[0026] It is apparent that the techniques described above can be used for a wide range of uses, from constructing textual messages, to controlling the entire or partial functionality of a portable radiotelephone. Such a system could be used to replace the need for a keypad on a portable radiotelephone, with all control and data input effected by the joystick device.

[0027] In yet a further embodiment of the present invention, a joystick lock facility is provided. This is to prevent unwanted selection of menus etc. through unintentional movement of the joystick device whilst stored in a pocket, handbag etc. A joystick lock menu is selected in the manner described above. Once locked, no further joystick inputs are accepted until the joystick device has highlighted a predetermined number of blocks, in a predetermined order, within a predetermined time period. Figure 4c shows one possible joystick lock screen, which is displayed once the joystick lock has been applied. In order to unlock the joystick, the joystick device must first highlight the block 410, followed by the block 411, the block 412 and finally the block 413. If a block is selected out of sequence, the sequence must be restarted. The blocks must be selected in the correct order, within a given time period in order for the joystick lock to be removed. The time period should allow the average user adequate time to accurately select the required blocks, whilst not being excessively long so as to reduce the risk of unintentional selection. Such a sequence is preferably such that it is unlikely to be carried out through unintentional movement of the joystick device, whilst in a pocket or handbag etc.

[0028] Figure 5 is a block diagram showing a portable radiotelephone 500 according to the present invention. A display device 501 is used for displaying or presenting textual or graphical information to a user. In an alternative embodiment of the present invention, the display device could be complemented by, or even replaced by, a speech synthesiser or other sensory means. The display device is connected to and controlled by a controller 502. The controller 502 accepts control signals from a joystick or other input device 503. The controller interprets the signals from the joystick device 503 which are made in response to information presented to the user on the display device 501. Optionally, a keypad 506 may also be connected to the controller 502. Such a keypad may be used for the inputting of further control signals, such as switching the portable radiotelephone on or off, or other typical functions found on such devices. A memory 504 is also connected to the controller 502. The memory 504 may be used to store, for example, textual messages constructed by the user, received messages from external users, user options, factory defaults etc. Finally, a telephone function module 505 is connected to the controller 502. The telephone function module

405 enables communication to be established with a telecommunications network, enabling calls to be made and received, textual or graphical messages to be sent or received, etc. The telephone function module 405 provides the typically functionality expected to found on a portable radiotelephone, as will be appreciated by those skilled in the art.

[0029] Figure 6 is a flow diagram showing an example of how the controller 502 of Figure 5 operates according to one embodiment of the present invention.

[0030] Step 600 causes a menu screen to be presented to the user, via the display device 401. In step 601, the controller 402 interprets movements made on the joystick device 403 to control the highlighting of menu items, as described above. The controller 402 decides when a selection of a menu item has been made according to the methods outlined above. Step 602 checks to see whether the menu or item selected has any associated submenu screens associated therewith. If a submenu screen is associated with the menu item selected, step 603 causes that submenu screen to be displayed. The user is then free to select an item from the submenu screen according to step 601. If, however, there is no submenu screen associated with the item selected, step 604 causes the function represented by the selected menu item to be performed, or selects the data represented by that menu item. The process is then repeated.

[0031] Although the present invention is described above with reference to one level of subscreen, it will be apparent that any number or arrangement of submenu screens could be used, providing that the lowest level of subscreen allows selection of a single character, number or function etc. In this way, complex character sets, such as Chinese, can be quickly and easily be used.

## Claims

1. Apparatus for selecting a character from a predetermined set of characters comprising:

a means for presenting to a user a first plurality of selectable choices, at least one of which represents a sub-set of said set of characters;  
input means for selecting one of said first plurality of selectable choices;  
wherein the means for presenting further presents to a user a second plurality of selectable choices, at least one of which represents a character of said selected choice; and  
wherein the input means further functions for selecting a character from said second plurality of selectable choices.

2. The apparatus of claim 1, wherein the input means is a directional input means having a predetermined number of predetermined directional inputs.

3. The apparatus of claim 1, wherein the means for presenting presents the selectable choices in a segmented arrangement, wherein each segment of said segmented arrangement corresponds to one of said predetermined directional inputs.

4. The apparatus of claim 1, 2 or 3, wherein the input means selects one of said selectable choices corresponding to a selected directional input.

5. The apparatus of claim 1, 2, 3 or 4, wherein no selectable choice is presented in respect of said second plurality of selectable choices in the segment corresponding to the selected one of said first plurality of selectable choices.

6. The apparatus of any preceding claim, wherein the input means is a directional joystick control.

7. The apparatus of any of claims 1 to 6, wherein the input means is an array of spatially aligned input actuators.

8. A portable radiotelephone comprising the apparatus of any of claims 1 to 7.

9. A method of selecting a character from a predetermined set of characters comprising:

presenting to a user a first plurality of selectable choices, at least one of which represents a sub-set of said set of characters;  
selecting one of said first plurality of selectable choices;  
presenting to a user a second plurality of selectable choices, at least one of which represents a character of said selected choice; and  
selecting a character from said second plurality of selectable choices.

10. A method according to claim 9, wherein the steps of selecting comprise accepting inputs from a predetermined number of predetermined directional inputs.

11. A method according to claim 10 wherein the steps of presenting further comprise presenting the selectable choices in a segmented arrangement, wherein each segment of said segmented arrangement corresponds to one of said predetermined directional inputs.

12. A method according to claim 11, wherein the steps of selecting further comprise selecting one of said selectable choices corresponding to a selected directional input.

13. A method according to claim 12, wherein the step

of presenting said second plurality of selectable choices comprises not presenting a selectable choice in the segment corresponding to the selected one of said first plurality of selectable choices.

5

14. An input means for providing directional signals to a device, the input means having a plurality of predetermined directional inputs and a controller for determining an actuation of the input means and for determining the direction of said actuation, wherein the controller further comprises:

a memory for storing a predetermined sequence of direction actuations; and  
a processor for blocking the directional signals to the device if a series of actuations of the input device do not match the predetermined sequence.

15

15. The input means of claim 14 wherein the input means is a joystick.

20

16. The input means of claim 14, wherein the input means is multi-positional device.

25

17. A method of supplying directional signals to a device from an input means having a plurality of predetermined directional inputs comprising:

storing a predetermined sequence of direction actuations;  
determining an actuation of the input means and determining the direction of said actuation;  
blocking the directional signals if a series of actuations of the input device do not match the predetermined sequence.

30

35

18. Apparatus for selecting a character from a predetermined set of characters substantially as hereinbefore described with reference to the accompanying drawings.

40

19. A portable radiotelephone having apparatus for selecting a character from a predetermined set of characters, substantially as hereinbefore described with reference to the accompanying drawings.

45

20. A method for selecting a character from a predetermined set of characters substantially as hereinbefore described with reference to the accompanying drawings.
